

UNL Department of Physics and Astronomy presents:

# Spin-Momentum Correlations, Aharonov-Bohm, and Color Entanglement in Quantum Chromodynamics

PRESENTED BY  
**CHRISTINE  
AIDALA,**  
University of  
Michigan

**THURSDAY**  
**MAY 5**  
**4:00 PM**  
**IN JH 136**

Refreshments will be served in the JH 1st Floor Vending Area at 3:30

## ABSTRACT

After the development of QCD in the last quarter of the 20th century, we are now in an exciting new era in which much more quantitative QCD calculations can be tested against increasingly sophisticated experimental measurements.

Advances include a greater focus on the *dynamics* of quarks and gluons within bound states and in the process of bound-state formation. Over the last two decades, studies initially focused on spin-momentum correlations in the proton have brought to the fore several deep, fundamental issues within QCD. We are now exploring the physical consequences of gauge invariance in QCD as a quantum field theory, analogous to the Aharonov-Bohm effects familiar to many from QED but predicted for any gauge-invariant quantum field theory. Given the unique non-Abelian nature of the QCD gauge group, these quantum mechanical phase effects lead to an exciting novel prediction of entanglement of quarks and gluons *across* QCD bound states. Exploratory measurements from the PHENIX experiment at the Relativistic Heavy Ion Collider and ongoing work at LHCb at the Large Hadron Collider will be highlighted. Comparing QED and QCD as Abelian vs. non-Abelian quantum field theories that admit bound states, possibilities to explore related effects in scattering from atomic systems will additionally be discussed.
